#### Abstract

A two-ligand system composed of the predesigned multivalent and complementary terpyridine-based ligands was exploited to construct heteroleptic metallo-supramolecules and to investigate the self-assembly mechanism. Molecular stellation of the trimeric hexagon $\left[\mathrm{Cd}_{6} \mathrm{~L}_{3}{ }_{3}\right]$ gave rise to the exclusive selfassembly of the star hexagon $\left[\mathrm{Cd}_{18} \mathbf{L}_{6}{ }_{6} \mathbf{L}_{3}{ }_{3}\right]$ through complementary ligand pairing between the ditopic and octatopic tectons. To understand how the intermolecular heteroleptic complexation influenced the self-assembly pathway, the star hexagon was truncated into two triangular fragments: $\left[\mathrm{Cd}_{12} \mathbf{L}^{1}{ }_{3} \mathbf{L}^{4}{ }_{3}\right]$ and $\left[\mathrm{Cd}_{12} \mathbf{L}_{3}^{1} \mathbf{L}^{5}\right]$. In the self-assembly of $\left[\mathrm{Cd}_{12} \mathbf{L}_{3}{ }_{3} \mathbf{L}^{4}\right]$, the conformational movements of hexatopic ligand $\mathbf{L}^{4}$ could be regulated by $\mathbf{L}^{1}$  to promote the subsequent coordination event, which was the key step to the successful multicomponent self-assembly. In contrast, the formation of $\left[\mathrm{Cd}_{12} \mathbf{L}_{3}{ }_{3} \mathbf{L}^{5}\right]$ was hampered by the geometrically mismatched intermediates.

## INTRODUCTION

Cooperative self-assembly prevails ubiquitously in construction and modulation of functional biomacromolecules in nature. ${ }^{1}$ The cooperativity typically involves conformational regulation of receptors ${ }^{2}$ or configurational preorganization of two or more building blocks ${ }^{3}$ to either increase or decrease binding affinity in subsequent binding events. The bio-inspired molecular design with cooperativity has been demonstrated in creation of artificial systems for applications in molecular recognition, ${ }^{4}$ catalysis, ${ }^{5}$ ion sensing, ${ }^{6}$ and so on. Besides, such a strategy could be applied to synthesis of sophisticated supramolecules in a well-controlled manner. ${ }^{7}$ However, it still remains a challenge to rationally design molecular building blocks for manipulation of inter- and intramolecular cooperative interactions.

Well-defined metal-ligand coordination geometry provides directional bonding to assemble molecular subcomponents in a preprogrammed way, which is a promising approach for construction of metallo-supramolecules. ${ }^{8}$ Aiming to further enhance geometrical diversity and complexity of assemblies, comprehension of self-assembly mechanisms ${ }^{9}$ and development of high-fidelity molecular recognition tools are essential for preventing the formation of undesired products in a multicomponent system. Hence, several self-selective coordination strategies have been developed for mono-, ${ }^{10}$ bi-, ${ }^{11}$ and tridentate ${ }^{12}$ ligands to fulfill the requirements. Among them, a variety of multivalent $2,2^{\prime}: 6^{\prime}, 2^{\prime \prime}$-terpyridine (tpy)-based ligands can be obtained by palladium-catalyzed cross-coupling reactions ${ }^{13}$ and serve as subcomponents for self-assembly of
giant metallo-supramolecules. ${ }^{14}$ In the supramolecular chemistry of metal-tpy complexes, a stepwise approach is commonly used to prepare predesigned metalloligands to eliminate mismatched assemblies during self-assembly. ${ }^{8 e, 15}$ Nevertheless, toward elevating the degree of molecular selfsorting, ${ }^{16}$ we have demonstrated that an equimolar mixture of $6,6^{\prime \prime}$-di(2,6-dimethoxyphenyl)tpy and unsubstituted tpy ligands can afford a sole heteroleptic complex upon addition of $\mathrm{Cd}^{\mathrm{II}}$ ions under ambient conditions. ${ }^{12 \mathrm{c}}$ The complementary ligand pair offers facile access to preparation of discrete metallomacrocycles as well as metallocages via multicomponent self-assembly. ${ }^{12 e, 17}$

To elucidate the importance of conformational regulation of multivalent ligands by intermolecular heteroleptic complexation, which resembles cooperative self-assembly in nature, herein we design and synthesize a suite of multivalent ligands $\mathbf{L}^{2}-\mathbf{L}^{5}$ and investigate the interplay in assembling with the complementary ligand $\mathbf{L}^{1}$. The star hexagon $\left[\mathrm{Cd}_{18} \mathbf{L}^{1}{ }_{6} \mathbf{L}_{3}{ }_{3}\right]$ consisting of the hexagonal core $\left[\mathrm{Cd}_{6} \mathbf{L}_{3}^{2}\right]$ is constructed in excellent yield via one-pot heteroleptic complexation. The selfassembly behavior of triangular fragments $\left[\mathrm{Cd}_{12} \mathbf{L}_{3}{ }_{3} \mathrm{~L}_{3}{ }_{3}\right]$ and

$L^{5}$

remained sharp and well split. In the aromatic region, in contrast to the downfield shifts of most of the signals, two doublets from 6,6"-tpy protons exhibited significant upfield shifts, indicating the formation of the octahedral coordination geometry of <tpy-Cd ${ }^{\text {II }}$-tpy> connectivity. ${ }^{18}$ Two sets of tpy signals with an integration ratio of $1: 1$ could be identified by using COSY and ROESY NMR techniques (Figures S37 and S38). Particularly, in the ROESY spectrum, the singlet from $H^{i}$ showed the correlation signal to the purple-labeled phenylene protons $H^{\mathrm{b}}$ so that two types of the bistpy complexes in the assembly could be unambiguously assigned. The methoxy groups ( $H^{j}$ ) and tert-butyl groups ( $\left.H^{\mathrm{k}}\right)$ still revealed sharp singlets after complexation (Figure S35), supporting the formation of a highly symmetric structure. In addition, the two ${ }^{113} \mathrm{Cd}$ NMR singlets at $\delta 268.80$ and 267.77 ppm clearly indicated that the self-assembly has two kinds of $\mathrm{Cd}^{\text {II }}$ centers (Figure S55). All the related peaks in the DOSY spectrum possessing the same diffusion coefficient ( $D=3.29 \times 10^{-10} \mathrm{~m}^{2}$ $\mathrm{s}^{-1}$ ) proved the formation of a single self-assembled structure in solution (Figure S51).
$\left[\mathrm{Cd}_{12} \mathbf{L}_{3} \mathbf{L}^{5}{ }_{3}\right]$ derived from $\left[\mathrm{Cd}_{18} \mathbf{L}_{6}^{1} \mathbf{L}^{3}{ }_{3}\right]$ is examined by titration experiments. The result indicates that the selective intermolecular complexation between $\mathbf{L}^{\mathbf{1}}$ and $\mathbf{L}^{4}$ leads to an appropriate conformation of tetratopic intermediate $\left[\mathrm{Cd}_{2} \mathrm{~L}^{\mathbf{1}} \mathbf{L}^{4}\right]$, which allows for the formation of the desired product.

## RESULTS AND DISCUSSION

The $6,6^{\prime \prime}$-substituted bis-tpy ligand $\mathbf{L}^{1}$ was prepared following the reported protocol. ${ }^{12 e}$ Multivalent ligands $\mathbf{L}^{2}, \mathbf{L}^{3}, \mathbf{L}^{4}$, and $\mathbf{L}^{5}$ (Scheme 1) were synthesized through a series of Pd-catalyzed Sonogashira and Suzuki-Miyaura coupling reactions (Schemes S1-S4), and the structural characterization was carefully done by NMR spectroscopy (Figures S1-S25) and high-resolution MALDI-TOF mass spectrometry (Figures S30-S33). The selfassembly experiment started with the tetratopic ligand $\mathbf{L}^{2}$, which was reacted with 2 equiv of $\mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2}$ in $\mathrm{CHCl}_{3} /$ $\mathrm{MeOH}(1 / 1, \mathrm{v} / \mathrm{v})$ at $25^{\circ} \mathrm{C}$ for 30 min . The reaction mixture was counterion-exchanged with excess $\mathrm{NH}_{4} \mathrm{PF}_{4}$ and then stirred at $25{ }^{\circ} \mathrm{C}$ for an additional 30 min (Figure 1a). After complexation, the ${ }^{1} \mathrm{H}$ NMR spectrum of the resultant complex

Figure 1. (a) Self-assembly of trimeric hexagon $\left[\mathrm{Cd}_{6} \mathrm{~L}_{3}^{2}\right]$ and ${ }^{1} \mathrm{H}$ NMR spectra of $\mathbf{L}^{2}$ and $\left[\mathrm{Cd}_{6} \mathrm{~L}_{3}^{2}\right]$. (b) ESI-MS spectrum of $\left[\mathrm{Cd}_{6} \mathbf{L}_{3}^{2}\right]$ and isotope pattern of $\left[\mathrm{M}-5 \mathrm{PF}_{6}\right]^{5+}$.

High-resolution electrospray ionization mass spectrometry (HR-ESI-MS) was used to verify the chemical composition of the complex. The ESI spectrum showed one series of peaks in agreement with the ions of trimeric hexagon $\left[\mathrm{Cd}_{6} \mathbf{L}_{3}{ }_{3}\right.$ ] at charge states from $5+$ to $10+$ (Figure 1b). In addition, electrospray ionization coupled with traveling wave ionmobility mass spectrometry (ESI-TWIM-MS) was utilized to obtain additional structural information. ${ }^{19}$ The ESI-TWIM-MS plot of $\left[\mathrm{Cd}_{6} \mathrm{~L}^{2}{ }_{3}\right]$ demonstrated a narrow drift time distribution for each charge state, indicating the absence of isomeric structures (Figure S61)..$^{20}$ The consistent correlation between the experimental and theoretical collision cross sections (CCSs) supported the presence of the proposed structure (Figure S63 and Table S2).

In geometrical stellation, ${ }^{21}$ a star hexagon can be produced by extending the edges of a hexagon until they intersect to form the new closed boundaries. On the basis of the successful self-assembly of $\left[\mathrm{Cd}_{6} \mathrm{~L}_{3}^{2}\right]$, we anticipated that a more complicated star-shaped metallo-supramolecule would be achieved through the complementary ligand pairing ${ }^{12 \mathrm{c}-\mathrm{e}}$ between ligands $\mathbf{L}^{1}$ and $\mathbf{L}^{3}$. As compared with $\mathbf{L}^{2}$, the octatopic ligand $\mathbf{L}^{3}$ has four additional coordination units to pair with $\mathbf{L}^{1}$ to form the external triangles. The complexation reaction of $\mathbf{L}^{1}$, $\mathbf{L}^{3}$, and $\mathrm{Cd}^{\mathrm{II}}$ ions in a precise molar ratio of $2: 1: 6$ was conducted to examine the multicomponent self-assembly process. As expected, the ${ }^{1} \mathrm{H}$ NMR spectrum of the resultant complex (Figure 2a) displayed two kinds of chemical environments for ligand $L^{1}$. Particularly, the peaks for the $3^{\prime}, 5^{\prime}$-tpy protons and the 2,6 -dimethoxyphenyl substituents ( $H^{e}$ and $H^{f}$ ) were split into two signals with an integration ratio of $1: 1$, suggesting the formation of two distinct heteroleptic complexes. The proper assignments for six sets of tpy protons, including two homoleptic and two heteroleptic complexes, were verified by COSY and ROESY experiments (Figures S39-S42). It is noteworthy that two triplets from the blue and green $5,5^{\prime \prime}$-tpy protons of $\mathbf{L}^{3}$ were assigned according to the ROESY spatial correlation with methoxy groups $H^{g}$ of $\mathbf{L}^{1}$, and the two heteroleptic connections were distinguished by

Figure 2. (a) Self-assembly of star hexagon $\left[\mathrm{Cd}_{18} \mathbf{L}^{1}{ }_{6} \mathbf{L}^{3}{ }_{3}\right]$ and ${ }^{1} \mathrm{H}$ NMR spectra of $\mathbf{L}^{3},\left[\mathrm{Cd}_{18} \mathbf{L}^{1}{ }_{6} \mathbf{L}^{3}{ }_{3}\right]$, and $\mathbf{L}^{1}$. The inset is the ${ }^{113} \mathrm{Cd}$ NMR spectrum of $\left[\mathrm{Cd}_{18} \mathrm{~L}^{\mathrm{L}}{ }_{6}{ }^{\mathrm{L}}{ }^{3}{ }_{3}\right]$. (b) ESI-MS spectrum and (c) ESI-TWIM-MS plot of $\left[\mathrm{Cd}_{18} \mathbf{L}^{1}{ }_{6} \mathbf{L}^{3}{ }_{3}\right]$.
the correlation with tert-butyl groups $H^{\mathrm{h}}$ of $\mathbf{L}^{3}$ (Figure S42). Relative to the uncomplexed $\mathbf{L}^{3}$, the blue and green $3^{\prime}, 5^{\prime}$-tpy protons exhibited significant upfield shifts due to the shielding effect deduced from the 2,6 -dimethoxyphenyl substituents; ${ }^{12 \mathrm{c}}$ on the other hand, the orange and purple $3^{\prime}, 5^{\prime}$-tpy protons showed downfield shifts because of coordination to the electron-deficient $\mathrm{Cd}^{\mathrm{II}}$ ions (Figure 2a). Consistently, the ${ }^{113} \mathrm{Cd}$ NMR analysis (Figure 2a and Figure S56) revealed two signals at $\delta 271.83$ and 271.21 ppm and two peaks at $\delta 242.66$ and 242.06 ppm with a $1: 2$ integration ratio, corresponding to the homoleptic and heteroleptic connections, respectively. The DOSY NMR spectrum indicated the existence of a sole species with $D=1.36 \times 10^{-10} \mathrm{~m}^{2} \mathrm{~s}^{-1}$ in $\mathrm{CD}_{3} \mathrm{CN}$ (Figure S52). Eventually, the formulation of $\left[\mathrm{Cd}_{18} \mathbf{L}_{6}^{1} \mathbf{L}^{3}{ }_{3}\right]$ was confirmed by 11 ESI-MS peaks derived from $11+$ to $21+$ ions (Figure 2b). In the ESI-TWIM-MS plot (Figure 2c), a single stair pattern with narrow drift time distributions implied that a discrete and rigid molecular star was assembled. The experimental average CCS also agreed well with the theoretical average CCSs generated from 300 simulated conformations (Figure S64 and Table S3).

To shed light on the self-assembly mechanism of $\left[\mathrm{Cd}_{18} \mathbf{L}^{1} \mathbf{L}^{3}{ }_{3}\right]$, the star-shaped complex was chopped into two
triangular fragments (Scheme 2) and their self-assembly processes were examined. Ligands $\mathbf{L}^{4}$ and $\mathbf{L}^{5}$ were synthesized

Scheme 2. Self-Assembly of Triangular Fragments $\left[\mathrm{Cd}_{12} \mathrm{~L}^{1}{ }_{3} \mathrm{~L}_{3}{ }_{3}\right]$ and $\left[\mathrm{Cd}_{12} \mathrm{~L}^{1}{ }_{3} \mathrm{~L}_{3}{ }_{3}\right.$ ]

by attaching two 4-terpyridylphenyl units at the para and ortho positions with respect to the purple-labeled 4-terpyridylphenyl substituents, respectively (Scheme 1). For construction of $\left[\mathrm{Cd}_{12} \mathbf{L}_{3} \mathbf{L}^{4}{ }_{3}\right]$, the hexatopic ligand $\mathbf{L}^{4}$ was assembled with $\mathbf{L}^{1}$ in the presence of $\mathrm{Cd}^{\mathrm{II}}$ ions. It was found that the desired triangle was produced in excellent yield under mild conditions.

The ${ }^{1} \mathrm{H}$ NMR characterization (Figure 3a) of $\left[\mathrm{Cd}_{12} \mathrm{~L}_{3} \mathrm{~L}^{4}{ }_{3}\right]$ exhibited three significant upfield shifts for the 2,6-dimethoxyphenyl protons ( $H^{e}$ and $H^{f}$ ) of $\mathbf{L}^{1}$ and the blue-labeled $3^{\prime}, 5^{\prime}-$ tpy portons of $\mathbf{L}^{4}$ as compared to the uncoordinated $\mathbf{L}^{1}$ and $\mathbf{L}^{4}$, which were similar to the observation in $\left[\mathrm{Cd}_{18} \mathbf{L}^{1}{ }_{6} \mathbf{L}^{3}{ }_{3}\right]$ that indicated the formation of the heteoleptic connectivity. The exclusive formation of the target complex was confirmed by five distinct ${ }^{1} \mathrm{H}$ NMR singlets at $\delta 9.04 \mathrm{ppm}$ (purple $3^{\prime}, 5^{\prime}$-tpy $H s$ of $\mathbf{L}^{4}$ ), $9.02 \mathrm{ppm}\left(3^{\prime}, 5^{\prime}\right.$-tpy $H \mathrm{~s}$ of $\mathbf{L}^{1}$ ), 8.93 ppm (orange $3^{\prime}, 5^{\prime}$-tpy Hs of $\mathbf{L}^{4}$ ), 8.47 ppm (blue $3^{\prime}, 5^{\prime}$-tpy Hs of $\mathrm{L}^{4}$ ), and $4.32 \mathrm{ppm}\left(\mathrm{OCH}_{3}\right.$ of $\left.\mathrm{L}^{4}\right)$ as well as three ${ }^{113} \mathrm{Cd}$ NMR peaks at $\delta$ 270.91, 269.98, and 241.35 ppm derived from two homoleptic and one heteroleptic $\mathrm{Cd}^{\mathrm{II}}$ nuclei (Figure 3a and Figure S57). The complete assignments were established by COSY and ROESY NMR (Figures S43-S46). The DOSY NMR spectrum (Figure S53) showed that all the relevant signals have the same diffusion coefficient $\left(D=2.89 \times 10^{-10} \mathrm{~m}^{2} \mathrm{~s}^{-1}\right)$. The assembled composition of $\left[\mathrm{Cd}_{12} \mathrm{~L}_{3}{ }_{3} \mathrm{~L}_{3}{ }_{3}\right]$ was unequivocally determined by the intense ESI-MS peaks generated from the $8+$ to $16+$ ions (Figure 3b), and its experimental average CCS of $1965.6 \pm 7.6$ obtained from the TWIM-MS analysis (Figure S62) was consistent with the modeled ones (Figure S65 and Table S4).

The complexation reaction of $\mathbf{L}^{1}$ (1 equiv), $\mathbf{L}^{5}$ (1 equiv), and $\mathrm{Cd}^{\mathrm{II}}$ ions (4 equiv) was conducted at $60^{\circ} \mathrm{C}$ to construct

Figure 3. (a) ${ }^{1} \mathrm{H}$ NMR spectra of $\mathbf{L}^{4},\left[\mathrm{Cd}_{12} \mathbf{L}^{1}{ }_{3} \mathbf{L}^{4}\right]$, and $\mathbf{L}^{1}$. The inset is the ${ }^{113} \mathrm{Cd}$ NMR spectrum of $\left[\mathrm{Cd}_{12} \mathrm{~L}^{1}{ }_{3} \mathrm{~L}^{4}{ }_{3}\right]$. (c) ESI-MS spectrum of $\left[\mathrm{Cd}_{12} \mathrm{~L}_{3}{ }_{3} \mathrm{~L}_{3}{ }_{3}\right]$ and isotope pattern of $\left[\mathrm{M}-10 \mathrm{PF}_{6}\right]^{10+}$.
$\left[\mathrm{Cd}_{12} \mathbf{L}_{3}{ }_{3} \mathbf{L}_{3}{ }_{3}\right]$ (Scheme 2). However, the resultant complex exhibited relatively poor solubility in common organic solvents, such as $\mathrm{MeOH}, \mathrm{MeCN}$, and $\mathrm{MeNO}_{2}$. The ${ }^{1} \mathrm{H}$ NMR spectrum (Figure S47) showed broad signals, which could not be properly identified and displayed multiple diffusion distributions $\left(D=(4.47-4.90) \times 10^{-10} \mathrm{~m}^{2} \mathrm{~s}^{-1}\right)$ in the DOSY experiment (Figure S54). The corresponding hydrodynamic radii were much smaller than those of $\left[\mathrm{Cd}_{6} \mathbf{L}^{2}{ }_{3}\right],\left[\mathrm{Cd}_{12} \mathbf{L}_{3}{ }_{3} \mathbf{L}^{4}{ }_{3}\right]$, and $\left[\mathrm{Cd}_{18} \mathbf{L}^{1}{ }_{6} \mathbf{L}_{3}^{3}\right]$ (Table S1). The ESI-MS spectrum (Figure S58) revealed that at least two species $\left[\mathrm{Cd}_{12} \mathbf{L}_{3}{ }_{3} \mathbf{L}_{3}^{5}\right]$ and $\left[\mathrm{Cd}_{10} \mathbf{L}_{4}{ }_{4} \mathbf{L}_{2}^{5}\right]$ were formed in the selfassembly process.

Given the aforementioned observations, the self-assembly of triangular fragments were significantly influenced by the position of the extra tpy units. To exclude the possibility of forming prevailing conformations, the theoretical AM1 semiempirical method was applied to evaluate the rotational barriers around the pivotal arene and the triple bond (black benzene rings labeled with e and $g$ in Scheme 1) for ligands $L^{4}$ and $\mathbf{L}^{5}$, respectively (Figures S66 and S67). The theoretical calculations showed that in both cases the rotational barriers around the triple bond are low ( $<2.2 \mathrm{kcal} / \mathrm{mol}$ ), and the side groups should be freely rotatable at the room temperature. Our previous study indicated that the substituted tpy ligand has a higher binding affinity to $\mathrm{Cd}^{\mathrm{II}}$ ions. ${ }^{12 \mathrm{c}}$ Hence, in the presence of an insufficient amount of $\mathrm{Cd}^{\mathrm{II}}$ ions, the formation of heteroleptic connections should dominate over that of homoleptic ones. Based on this assumption, the stoichiom-etry-controlled experiment was designed for the mechanistic study. Instead of using 4 equiv of $\mathrm{Cd}^{\mathrm{ll}}$ ions, 2 equiv was applied to trapping the intermediate species. An equimolar mixture of $\mathrm{L}^{1}$ and $\mathrm{L}^{4}$ was reacted with 2 equiv of $\mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2}$. The ESI-MS spectrum showed two peaks generated form the 3+ and 4+ ions of $\left[\mathrm{Cd}_{2} \mathbf{L}^{1} \mathbf{L}^{4}\right]$ (Figure S59a), implying that two heteroleptic connections between $\mathbf{L}^{1}$ and $\mathbf{L}^{4}$ were formed. Because of the geometrical complementarity, the blue-labeled tpy moieties of $\mathbf{L}^{4}$ were supposedly pinched by $\mathbf{L}^{1}$ to afford the tetratopic species $\left[\mathrm{Cd}_{2} \mathbf{L}^{1} \mathbf{L}^{4}\right]$ (Scheme 3a) where the internal rotation of the outer coordination sites of $\mathrm{L}^{4}$ relative to the central scaffold was hampered by the dinuclear ring. The

Scheme 3. (a) Proposed Self-Assembly Pathway for $\left[\mathrm{Cd}_{12} \mathrm{~L}^{1}{ }_{3} \mathrm{~L}^{4}{ }_{3}\right]$ and (b) Possible Structure of $\left[\mathrm{Cd}_{2} \mathrm{~L}^{1} \mathrm{~L}^{5}\right]$

restricted conformation would facilitate the following cooperative coordination to form complex $\left[\mathrm{Cd}_{12} \mathbf{L}_{3}{ }_{3} \mathbf{L}^{4}\right.$ ] because the entropy loss from the frozen rotation has been satisfied by the intermolecular heteroleptic complexation. The UV-vis titration was conducted to further corroborate the proposed twostep mechanism. Indeed, an isosbestic point at 326 nm was observed with increasing amount of $\mathrm{Cd}^{\mathrm{II}}$ up to 2 equiv, indicating the equilibrium between the uncomplexed ligand mixture and intermediate $\left[\mathrm{Cd}_{2} \mathbf{L}^{1} \mathbf{L}^{4}\right]$ (Figure S60a). The isosbestic point was slightly shifted to 321 nm by further addition of $\mathrm{Cd}^{\mathrm{II}}$ to the stoichiometric point, suggesting that a new equilibrium between intermediate $\left[\mathrm{Cd}_{2} \mathbf{L}^{1} \mathbf{L}^{4}\right]$ and triangle $\left[\mathrm{Cd}_{12} \mathrm{~L}_{3}{ }_{3} \mathrm{~L}^{4}{ }_{3}\right]$ was established (Figure S60b).

To reflect how the restricted conformation of $\left[\mathrm{Cd}_{2} \mathbf{L}^{1} \mathbf{L}^{4}\right]$ influences the stability of the trimeric hexagonal core held by six homoleptic $\mathrm{Cd}^{\mathrm{II}}$ connections, complexes $\left[\mathrm{Cd}_{6} \mathrm{~L}^{2}{ }_{3}\right]$ and $\left[\mathrm{Cd}_{12} \mathbf{L}_{3}{ }_{3} \mathbf{L}^{4}{ }_{3}\right]$ in $\mathrm{CD}_{3} \mathrm{CN}\left(1.2 \times 10^{-4} \mathrm{M}\right)$ were titrated with $\mathrm{Cd}(\mathrm{OTf})_{2}$ (Figures S68-S70). The ${ }^{1} \mathrm{H}$ NMR analyses indicated that $\left[\mathrm{Cd}_{6} \mathbf{L}^{2}{ }_{3}\right]$ was completely dissociated into $\left[\mathrm{Cd}_{4} \mathrm{~L}^{2}\right]$ when 12 equiv of $\mathrm{Cd}(\mathrm{OTf})_{2}$ with respect to each homoleptic $\mathrm{Cd}^{\mathrm{II}}$ center was added. By contrast, 32 equiv of $\mathrm{Cd}(\mathrm{OTf})_{2}$ was needed to fully break up $\left[\mathrm{Cd}_{12} \mathrm{~L}_{3}{ }_{3} \mathrm{~L}_{3}{ }_{3}\right]$ into $\left[\mathrm{Cd}_{6} \mathbf{L}^{1} \mathbf{L}^{4}\right]$. Because $\left[\mathrm{Cd}_{12} \mathrm{~L}^{1}{ }_{3} \mathbf{L}_{3}{ }_{3}\right]$ and $\left[\mathrm{Cd}_{6} \mathrm{~L}^{2}{ }_{3}\right]$ have the same core structure, the enhanced stability of $\left[\mathrm{Cd}_{12} \mathbf{L}^{1}{ }_{3} \mathbf{L}_{3}^{4}\right]$ could be attributed to its $\mathbf{L}^{1}$-regulated conformation. The self-assembly of $\left[\mathrm{Cd}_{12} \mathrm{~L}_{3}{ }_{3} \mathrm{~L}_{3}{ }_{3}\right]$ might be involved in chelate and/or interannular cooperativity, ${ }^{22}$ but a more detailed investigation of each isolated binding event is required to quantitatively identify the real occurrence.

On the other hand, when a $1: 1$ mixture of $L^{1}$ and $L^{5}$ was treated with 2 equiv of $\mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2}$, the ESI-MS study showed the formation of $\left[\mathrm{Cd}_{2} \mathbf{L}^{1} \mathbf{L}^{5}\right]$ (Figure S 59 b ). However, in comparison with $\left[\mathrm{Cd}_{2} \mathbf{L}^{1} \mathbf{L}^{4}\right]$, no matter where the heteroleptic complexation occurred, the intermediate $\left[\mathrm{Cd}_{2} \mathbf{L}^{1} \mathbf{L}^{5}\right]$ would hinder the self-assembly of target triangle $\left[\mathrm{Cd}_{12} \mathrm{~L}_{3}{ }_{3} \mathrm{~L}_{3}{ }_{3}\right]$ upon treatment with additional $\mathrm{Cd}^{\mathrm{II}}$ ions. The possible structure of [ $\mathrm{Cd}_{2} \mathbf{L}^{1} \mathbf{L}^{5}$ ] is illustrated in Scheme 3b, where the orange and purple tpy units of $\mathbf{L}^{5}$ were complexed with $\mathbf{L}^{1}$ to generate a distorted dinuclear macrocycle. Accordingly, the model compound $L^{6}$ was synthesized to verify whether the heteroleptic complexation with $\mathbf{L}^{1}$ could take place to produce the geometrically mismatched macrocycle (Figure 4 and Scheme S5). Notably, the complexation reaction of $\mathbf{L}^{1}$ and

Figure 4. Self-assembly and ${ }^{1} \mathrm{H}$ NMR spectrum of the distorted dinuclear macrocycle, $\left[\mathrm{Cd}_{2} \mathrm{~L}^{1} \mathbf{L}^{6}\right]$.
$\mathbf{L}^{6}$ with $\mathrm{Cd}^{\mathrm{II}}$ at $25^{\circ} \mathrm{C}$ afforded a mixture of $\left[\mathrm{Cd}_{2} \mathbf{L}^{1} \mathbf{L}^{6}\right]$ (minor) and $\left[\mathrm{Cd}_{4} \mathrm{~L}_{2}^{1} \mathrm{~L}^{6}{ }_{2}\right]$ (major) (Figure S48). After 1 h of heating at $80^{\circ} \mathrm{C}$, the mixture was completely converted into $\left[\mathrm{Cd}_{2} \mathrm{~L}^{1} \mathrm{~L}^{6}\right]$ whose structure was established by NMR and ESI-MS (Figure 4 and Figures S48-S50).

To gain insights into the kinetic aspect, the ligand exchange reaction between a mononuclear heteroleptic complex ( $\left[\mathrm{CdL}^{\mathrm{A}} \mathbf{L}^{\mathrm{B}}\right]\left(\mathrm{PF}_{6}\right)_{2}$ ) and a free 6,6"-di(2,6-dimethoxyphenyl)tpy ligand $\left(\mathbf{L}^{\mathbf{A}}\right)$ was investigated by ${ }^{1} \mathrm{H}$ exchange spectroscopy (EXSY) NMR experiments (Figure S71). The exchange rate $\left(k_{\mathrm{ex}}\right)$ was estimated to be $1.6 \times 10^{-2} \mathrm{~s}^{-1}$ at $25^{\circ} \mathrm{C}$ in $\mathrm{CD}_{3} \mathrm{CN} /$ $\mathrm{CDCl}_{3}(1 / 1, \mathrm{v} / \mathrm{v})$, which is similar to that $\left(1.9 \times 10^{-2} \mathrm{~s}^{-1}\right)$ between $\left[\mathrm{Pd}(\mathrm{py})_{4}\right]^{2+}(\mathrm{py}=$ pyridine) and free pyridine in $\mathrm{CD}_{3} \mathrm{CN} .^{23}$ Even though the exchange rate for monotopic ligands is fast, the misassembled yet stable intermediates deduced from multivalent ligand $\mathbf{L}^{5}$ and ditopic ligand $\mathbf{L}^{1}$ still interrupted the self-assembly of $\left[\mathrm{Cd}_{12} \mathrm{~L}_{3}{ }_{3} \mathrm{~L}_{3}^{5}\right]$.

## CONCLUSIONS

In summary, a family of multivalent tpy-based ligands $\mathbf{L}^{2}-\mathbf{L}^{5}$ were successfully synthesized through Pd-catalyzed crosscouplings and utilized to study the complementary interplay with $\mathbf{L}^{1}$. The self-assembly of trimeric hexagon $\left[\mathrm{Cd}_{6} \mathbf{L}_{3}{ }_{3}\right]$ was achieved under mild conditions and served as a basis for the following molecular stellation. The star hexagon $\left[\mathrm{Cd}_{18} \mathbf{L}^{1}{ }_{6} \mathbf{L}_{3}{ }_{3}\right]$ was constructed via multicomponent self-assembly, and its structure was established by NMR, ESI-MS, and ESI-TWIMMS. To understand the assembly mechanism, the self-assembly behavior of two triangular fragments derived from $\left[\mathrm{Cd}_{18} \mathbf{L}^{1}{ }_{6} \mathbf{L}^{3}{ }_{3}\right.$ ] was investigated by trapping possible intermediates and titration experiments. The mechanistic study manifested that the intermolecular heteroleptic complexation of $\mathbf{L}^{4}$ or $\mathbf{L}^{5}$ with $\mathbf{L}^{1}$ plays a pivotal role in construction of the corresponding triangles. The conformational regulation of $\mathbf{L}^{4}$ by $\mathbf{L}^{1}$ could facilitate the formation of the desired triangle $\left[\mathrm{Cd}_{12} \mathrm{~L}_{3}{ }_{3} \mathrm{~L}_{3}{ }^{3}\right.$ ] whose assembly process exhibited cooperative coordination. On the other hand, the geometrically mismatched intermediates impeded the self-assembly pathway leading to $\left[\mathrm{Cd}_{12} \mathrm{~L}^{1}{ }_{3} \mathbf{L}_{3}{ }_{3}\right]$. We anticipate that this study would
lay the foundation for rationally manipulating metal-mediated cooperative interactions.

## Notes

The authors declare no competing financial interest.

## ACKNOWLEDGMENTS

This research was supported by the Ministry of Science and Technology of Taiwan (MOST106-2628-M-002-007-MY3). We gratefully thank Ms. S.-L. Huang at MOST (National Taiwan University) for the assistance in NMR experiments.
